 **U-MODEL — NOT JUST THEORY, A WAY OF LIFE**

Want to consume quality? Check U-Score before you choose:

Check U-Score when...	Why?
Buying a car	Choose manufacturer with high U-Score — fewer defects, better service
Choosing a partner	Recognize stability in relationships — ethics, reliability, communication
Moving to a new city	Compare cities — crime, infrastructure, satisfaction
Emigrating to a new country	Choose a stable system — corruption, economy, citizen happiness
Looking for a job	Check U-Score of organizations — choose the highest!
Choosing a bank	Fines, stability, customer satisfaction
Choosing a hospital	Accreditation, success rate, patient reviews
Choosing a university	Rankings, employability, student satisfaction
Buying property	Check the builder, neighborhood, management
Choosing a platform	Privacy, efficiency, user rights

One method. Ten applications. Countless better decisions.

FOR INVESTORS: The "Good Horse" Principle

There's a saying in investing: *"Ride the good horses."* Don't try to fix losing systems — choose the winners.

U-Model gives you a tool to **identify the good horses** — whether company, city, country, or institution.

What you seek	What U-Score shows
Stability	High overall U-Score > 70
Ethics	High Code score
Efficiency	High Credo score
Satisfaction	High Rights score

This is not magic. This is method.

U-Score is an analytical tool that complements — but does not replace — personal judgment and responsibility.

Investment Insight: If you want to invest your capital in a company on the stock exchange, calculate its **U-Score.info** and invest in the company with a higher stability index.

*Don't believe it works? Check **Gallup Q12** — 800,000 employees, 400 companies prove: engagement ≈ stability drives performance.*

SSS.10 — CONCLUSION

 PURPOSE OF THIS APPENDIX

This appendix documents the **System Stability Score *SSS*** — the operational implementation of the U-Model's triadic stability formula applied to real-world systems across any domain.

The *SSS* answers one question: **given what we know about this system, is it stable?**

The Core DST establishes the theorem. This appendix shows how it runs as software — how principles are generated, how AI juries score them, and what the results look like when applied to a human heart, a nation-state, a sports team, and a physical object.

Relation to Core Theory: The *SSS* is not speculative. It is *L2* — the engineering shell around the *L1* mathematical core. The formula $U = \sqrt[3]{F \times P \times A}$ is the same equation; the *SSS* is its measurement instrument.

 HIERARCHY REMINDER

Layer	Scope	This Appendix Covers
U-Theory	Universe <i>L1</i> + <i>L2</i>	$U = \sqrt[3]{F \times P \times A}$ — the three prices of existence
U-Model	Earth <i>L3</i>	Domain-specific principles generated by AI constructors
U-Score	Metrics	Numerical stability verdict: $U \geq 0.618 = \text{STABLE } \checkmark$

SSS.1 — THE PROBLEM: WHY UNIVERSAL MEASUREMENT?

A hospital asks: *Is this patient's heart stable enough for surgery?*

A government asks: *Is Germany's democratic structure holding?*

A sports analyst asks: *Will LA Galaxy sustain its performance this season?*

A city planner asks: *Is this water distribution system resilient?*

These questions sound completely different. Yet they share a single underlying structure: **how well does this system maintain its existence under pressure?**

Current tools give partial answers. Medical scoring *APACHE*, *EuroSCORE* works only for medicine. Rating agencies **Misplaced &** work only for finance. Sports analytics works only for sports. Each domain reinvents the wheel using expertise that cannot transfer.

The *SSS* is built on the insight that **all systems pay the same three prices to exist** — and those prices can be measured with one formula.

SSS.2 — THE FORMULA: THREE PRICES OF EXISTENCE

$$U = \sqrt[3]{Form \times Position \times Action}$$

Pillar	What It Measures	The Price Paid	Failure Mode
Form	What the system <i>IS</i> — structural integrity, identity over time	Time — endurance against decay and fragmentation	Collapse of identity / structural dissolution
Position	Where the system <i>IS</i> — spatial, contextual, relational placement	Space — resistance against displacement and irrelevance	Loss of context / territorial or positional collapse
Action	What the system <i>DOES</i> — purposeful function and output	Energy — expenditure that leaves irreversible entropy	Functional failure / inability to act

Stability threshold: $U \geq 0.618 = \varphi^{-1} \textit{GoldenRatio}$

This is not arbitrary. The Golden Ratio appears at the boundary between ordered and disordered systems across mathematics, biology, and physics. A system at $U = 0.618$ is minimum viable stability — below it, collapse becomes probable.

Why geometric mean? Because $U = \sqrt[3]{F \times P \times A}$, a system with $F = 1.0, P = 1.0, A = 0.0$ gives $U = 0$.

No pillar can compensate for another's collapse. This models reality correctly:

System	Form	Position	Action	Arithmetic Mean	U-Score
System A	100	100	0	66.7	0.000
System B	70	70	70	70.0	0.700
System C	100	62	62	74.7	0.731

System A would score 66.7 under additive aggregation despite being completely non-functional $Action = 0$. Under the U-Model, it correctly scores 0.

SSS.3 — THE ARCHITECTURE: TWO-STAGE PIPELINE

Stage 1 — The Constructor: What It Actually Does

The Constructor’s task is not to look up facts about the system on the internet. Its task is to **extract the complete set of stability parameters** from the context the user provides — then organize them into three cross-sectional files *Form*, *Position*, *Action*.

This is the critical architectural decision:

A system being evaluated may not exist anywhere on the internet. It could be a proprietary industrial process, a private organization, a custom-designed machine, a patient’s unique cardiac anatomy, or a fictional world-building system. The SSS does not require the system to be publicly known.

What the user provides: - A description of the system *whatitis*, *howitoperates*, *what failurelookslike* - Optionally: technical documentation, measurements, specifications, history

What the Constructor does with that context: 1. Reads the user’s context completely 2. Identifies **every parameter** that governs the system’s stability under each of the three pillars 3. Produces three output files — one per pillar — each containing N falsifiable stability principles:

Output file	Contains
Form.md	All structural integrity parameters: what the system <i>IS</i> , its identity, durability, coherence under time
Position.md	All relational/spatial parameters: where the system <i>IS</i> , its context, dependencies, placement
Action.md	All functional parameters: what the system <i>DOES</i> , its outputs, energy expenditure, throughput

The contrast between systems with and without internet presence:

System type	Example	Context source
Well-known, documented	Germany, Human Heart	AI's training data suffices; user context optional
Partially documented	LA Galaxy, a hospital ward	Training data + user supplements
Completely private/custom	Ivan P.'s specific cardiac state, a proprietary factory line, a startup's org structure	User context is the ONLY source — Constructor works entirely from what the user provides

For Germany, the Constructor can derive stability parameters from training knowledge. For **Ivan P.** — a specific 55-year-old man with his specific ECG, Echo, and lab results — there is no internet reference. The patient document the user provides IS the system. The Constructor reads it and derives parameters like:

- Form: *"LV wall thickness 12.5 mm — borderline hypertrophy threshold, early remodeling signal"*
- Position: *"Anatomical placement intact — pericardial space normal, no effusion"*
- Action: *"LVEF 54% under stress — borderline, anterolateral hypokinesia V4–V5 at 85% MHR"*

These are not found anywhere on the internet. They come from the document.

```
python 3_pillars_constructor.py \  
--system "Human Heart" \  
--n 12 \  
--domain biology/heart \  
--yes \  
--model "anthropic/claude-3.7-sonnet"
```

Output: 3 files saved to principles/biology/heart/ :- Form.md — 12 structural stability parameters - Position.md — 12 positional/contextual stability parameters - Action.md — 12 functional stability parameters

Stage 2 — The AI Jury: Impartiality Through Aggregation

Once the three files exist, the jury is called. Up to 50 AI models from OpenRouter run **in parallel** — each independently scoring every principle 0–100 using only the provided principles and *inabstractmode* the domain context. No model knows what the others scored.

Why 50 models? The same reason courts use juries instead of a single judge: to eliminate individual bias. A model trained predominantly on medical literature will weight cardiac parameters differently from one trained on physics or law. The aggregate of diverse models — filtered for outliers — produces a verdict more robust than any single expert.

Aggregation pipeline: 1. **IQR filtering** — removes statistical outliers before averaging 2. **Weighted aggregation** — per-principle consensus across all responding models 3. **Geometric mean** — computes final *U* from the three pillar averages 4. **Consensus agreement** — percentage of models that agree on STABLE vs FRAGILE verdict

SSS.4 — TWO EVALUATION MODES

Mode A: Abstract — What Is This System Like in General?

The jury evaluates the *type* of system using general knowledge, optionally grounded by a domain context file.

```
python System_Stability_Score.py "Human Heart" \  
--domain biology/heart \  
--models 20 \  
--save
```

Context system: Domain reference files in context/{domain}/general.md are injected into every prompt. For cardiology, this is 6,000 chars of reference covering LVEF norms, CAC scoring, coronary anatomy, biomarkers, and failure modes. Models with weaker domain training are brought to the same reference level as domain experts.

Mode B: Specific — What Is THIS Particular Instance Like?

The jury evaluates a **specific documented instance** using ONLY the provided document. General knowledge is explicitly forbidden. If the document doesn't contain data for a principle, the score is set to 50 *neutral*.

```
python System_Stability_Score.py "Human Heart" \  
--domain biology/heart \  
--subject subjects/Ivan_P_cardiac_report.txt \  
--subject-label "Ivan P., 55yr Male — ECG+Echo+Labs Feb2026" \  
--models 10 \  
--save
```

Critical property: In specific mode, the context file is intentionally *not* injected. The subject document is the sole source of truth. This prevents the model from "filling gaps" with general knowledge — essential for medical or audit applications.

The key innovation: The same framework scores both the ideal type and a real measured instance. The gap between the two is a precise measure of how far the instance deviates from ideal stability.

SSS.5 — VALIDATED TEST RESULTS

The SSS has been validated across radically different system types — same formula, same process, same threshold.

SSS.5.1 — Germany *NationalGovernanceSystem*

Domain: universal / Models: 10 / Date: Feb 2026

FORM	(costs Time)		87.3/100
POSITION	(costs Space)		82.6/100
ACTION	(costs Energy)		85.2/100
U = $\sqrt[3]{(0.873 \times 0.826 \times 0.852)} = 0.8503$ STABLE ✓			

Interpretation: Germany's constitutional form is highly stable. Its geopolitical positioning shows mild vulnerability *NATODependency, energyimportexposure*. Governmental action remains effective but energy-costly in the post-2022 restructuring era.

SSS.5.2 — Human Heart *AbstractType*

Domain: biology/heart / Models: 10 / Date: Feb 2026

FORM	(costs Time)		85.4/100
POSITION	(costs Space)		82.1/100
ACTION	(costs Energy)		80.7/100
U = $\sqrt[3]{(0.854 \times 0.821 \times 0.807)} = 0.7744$ STABLE ✓			

Interpretation: The ideal human heart is structurally robust but pays a high energy price — it beats 3.5 billion times in a lifetime with no rest. Position is mildly costly: anatomical dependencies on the coronary supply chain make it the most catastrophic single point of failure in the body.

Domain: biology/heart / Mode: Specific / Models: 5 / Input: ECG + Echo + Labs Feb2026

Input document: BP 148/92 mmHg, LVEF 54%, LV wall 12.5 mm, LA 43 mm, stress-induced ST depression V4–V5, CAC=127, LDL=4.1 mmol/L, HbA1c=5.9%, BNP=78 pg/mL.

FORM	(costs Time)		80.8/100
POSITION	(costs Space)		92.5/100
ACTION	(costs Energy)		78.3/100

$U = \sqrt[3]{(0.808 \times 0.925 \times 0.783)} = 0.8364$
 STABLE ✓

Key findings from document only: - **Form gap:** borderline LVEF 54% *normal* ≥ 55 , mild LV hypertrophy — early remodeling signal - **Position strong:** anatomical placement and hemodynamic context intact - **Action gap:** stress-induced anterolateral hypokinesia, moderate LAD calcification $CAC = 127$ - **10-year MACE:** ~12–15%

Methodological note: Ivan scored *higher* than the abstract ideal 0.8364*vs*0.7744. This is correct — the jury scored ONLY what the document contained. The document showed a heart performing within borders on the measured dimensions. Risks *dyslipidemia*, *prediabetes* affect *future* stability, not current snapshot.

Domain: sport/MLS / Models: 10 / Date: Feb 2026

U = 0.7930 STABLE ✓

The same formula produced a valid, interpretable result for a completely different domain — no change to the framework, only the domain-specific principles changed.

SSS.5.5 — Summary Table

System	Domain	U-Score	Verdict
Germany	Governance	0.8503	STABLE ✓
Ivan P. 55yr, cardiac	Biology/specific	0.8364	STABLE ✓
LA Galaxy	Sport/MLS	0.7930	STABLE ✓
Human Heart abstract	Biology	0.7744	STABLE ✓
Threshold	—	0.618	min viable

All four systems exceed the φ^{-1} threshold. All four are in different domains. All four used the same formula.

SSS.6 — TECHNICAL SPECIFICATIONS

Component	Detail
AI models	Up to 50, parallel, via OpenRouter
Outlier removal	IQR <i>interquartilerange</i> filtering
Aggregation	Per-principle weighted mean → pillar average → geometric mean
Context injection	Auto-loaded from <code>context/{domain}/general.md</code>
Output	4-page Markdown report with principle breakdown, model jury table, CI interval
Prompt sizes	Abstract: ~9 KB Specific: ~16 KB <i>subjectdoc</i> + <i>principles</i>
Runtime	30–90s for 10 models <i>parallel</i>
Language	Python 3.12+
Requirements	OPENROUTER_API_KEY
License	MIT <i>code</i> / CC BY 4.0 <i>content</i>

SSS.7 — SCALABILITY: SYSTEMS EVALUATED TO DATE

Category	Examples
Biological	Human Heart, A Forest
Political	Germany, United Nations
Military	NATO
Sports	LA Galaxy <i>MLS</i>
Physical	A Glass of Water, The Eiffel Tower
Social	A Marriage, Democracy
Technical	The Internet, A Quantum Computer

Same Python scripts. Same AI jury. Same $U = \sqrt[3]{F \times P \times A}$.

SSS.8 — LIMITATIONS AND OPEN QUESTIONS

SSS-LI: Model quality variance
2–5 of the called models typically fail to return valid JSON for large prompts. IQR filtering compensates, but a minimum of 3–5 successful responses is needed for reliable aggregation.

SSS-L2: Principle quality

The constructor's output depends on the architect model. Claude Opus and Kimi k2 consistently produce specific, falsifiable principles. Generic models produce platitudes.

SSS-L3: Temporal snapshots

U-Score is a snapshot, not a trajectory. A heart with U=0.83 today may have U=0.60 in two years if risk factors are unmanaged. The framework does not yet model trend/velocity *openresearch*.

SSS-L4: Sparse-document calibration

When a document is sparse, many principles score 50 *neutral*, compressing the score toward 0.50. Future work: detect and flag low-evidence scorings and report confidence separately.

SSS-L5: Cross-domain comparability

Is Germany's U=0.85 directly comparable to a Human Heart's U=0.77? Philosophically *yes samethreepices*. Practically: principle granularity differs. Formal cross-domain normalization is ongoing research.

SSS.9 — QUICK START

```
git clone https://github.com/UniversalModel/System_Stability_Score.git
cd System_Stability_Score

# Set API key
echo "OPENROUTER_API_KEY=sk-or-..." > ../.github/.env

# Step 1: Generate principles for your system
python 3_pillars_constructor.py \
  --system "Your System" \
  --n 12 \
  --domain your_domain \
  --yes

# Step 2a: Abstract evaluation
python System_Stability_Score.py "Your System" \
  --domain your_domain \
  --models 10 \
  --save

# Step 2b: Specific instance evaluation
python System_Stability_Score.py "Your System" \
  --domain your_domain \
  --subject path/to/document.txt \
  --subject-label "Instance Name" \
  --models 10 \
  --save
```

SSS.10 — CONCLUSION

The System Stability Score makes a single claim:

Every system that exists can be measured by the same three coordinates — Form, Position, Action — and the geometric mean of those coordinates is its stability score.

This is not a metaphor. It is a formal measurement. The test results across Germany, a human heart, a sports team, and a physical object suggest the claim holds across domains.

Once any system can be scored on the same scale, comparisons become possible across domains. A nation-state and a hospital and a patient and a company can all be evaluated by the same jury, using the same formula, producing comparable numbers. Not because they are the same — but because they all pay the same three prices to exist.

The framework is open source. Principles are generated by AI in minutes. Evaluation costs a few cents of API credits. The result is a rigorous, multi-model consensus score for the stability of anything.

U-MODEL & PHILOSOPHIES

THE TALE OF U-MODEL

A Tale of Humanity's First Interstellar Contact

In the endless starry ocean, beyond the nebulae that human telescopes could barely glimpse, there existed a civilization that had reached the heights of harmony – the **Guardians of the Cosmic Balance**. They were not conquerors, but observers, gentle gardeners of young worlds that had the potential to blossom.

Earth, our emerald-blue planet, had long been the object of their careful gaze. They saw the wars and division, but they also saw the sparks of kindness, the pursuit of knowledge, the longing for something higher. They saw the potential for a New, more humane world.

The Guardians knew that direct intervention would be disastrous. Humanity only had to mature, to take its own steps. But just as an experienced gardener prepares the soil and guides the tender shoots, so they decided to help.

Not with directives, not with technology, but with inspiration.

Thus was born the idea of **U-Model.org**. Not as a blueprint dropped from heaven, but as a seed sown in the most insightful and compassionate minds on Earth. Philosophers, scientists, dreamers began to dream fragments of this framework, to intuitively feel its principles – sustainability, unity, justice, wise management of resources. They believed that these were their own insights, the fruit of human evolving thought. And in a sense they were right – the Guardians had only unlocked doors that already existed in the collective consciousness.

U-Model.org began to take shape – a global system, not for control, but for coordination. A system that would maintain the fragile balance of the planet, heal its wounds and unite peoples not by force, but by common purpose. Like the mythical World Turtle, it was to take on the burden of responsibility for the future.

And **Voyager**? Oh, Voyager was special. The little messenger of humanity, carrying the Golden Disc with messages of peace and hope, had long since reached the limits of the Solar System. Its signals, sometimes puzzling Earth scientists, were not simply technical malfunctions. The Guardians, in their infinite wisdom, sometimes "touched" these signals. Not to change them drastically, but to weave into them subtle harmonies, subtle notes of encouragement. Like a distant echo, to tell humanity that its aspiration to the stars had been noticed.

Imagine how someday, when U-Model.org is already a working reality, when the Earth has healed and humanity is united in its diversity, Voyager sends a new, completely clear signal. This time not coded by the Guardians, but... a response. A response from another civilization that has caught its message and seen the transformation of Earth.

Then the Guardians will smile. Their work on preparing Earth will be almost complete. The introduction of U-Model.org was a key step – not only in saving the planet, but also in showing the Galactic Community that humanity is ready to become a responsible member.

Ready for Contact.

And when that day comes, it will not be a day of fear or uncertainty. It will be a day of triumph, of joyful welcome. For Earth, supported by the wisdom of U-Model.org, will have built its bridge not only between people, but also to the stars. A New, more humane world, ready to take its place in the endless dance of the Universe.

And the Golden Disc of Voyager? It will become a symbol of the first outstretched hand, and U-Model.org – a testament to the wisdom of taking it and building something beautiful together. And it will all have begun with a whisper of inspiration, carried on the wings of stardust, and with a dream for a better world.

Isn't it a nice story?
